Higher-order spectra, or polyspectra, are defined as the multidimensional Fourier transforms of higher-order cumulants. Cumulants, or polyspectra, of Gaussian processes, of order > 2 , are identically zero. Thus, in theory, HOS are high signal-to-noise-ratio domains, where system identification or signal reconstruction can be performed.

Higher Order Spectra Analysis

Higher-order spectra which are defined in terms of the higher-order moments or cumulants of a signal, contain this additional information. The Higher-Order Spectral Analysis (HOSA) Toolbox provides comprehensive higher-order spectral analysis capabilities for signal processing applications.

Further, in the case of harmonic processes, the power spectrum and parametric methods based on the autocorrelation are usually sufficient, unless the data contain narrow-band Gaussian components. Higher-order cumulants and spectra are useful to isolate specific types of coupling (quadratic, cubic, etc.).

In statistics, the term higher-order statistics (HOS) refers to functions which use the third or higher power of a sample, as opposed to more conventional techniques of lower-order statistics, which use constant, linear, and quadratic terms (zeroth, first, and second powers). The third and higher moments, as used in the skewness and kurtosis, are examples of HOS, whereas the first and second moments, as used in the arithmetic mean (first), and variance (second) are examples of low-order ...

Higher order spectra were originally introduced as spectral representations of cumulants or moments of ergodic random processes. They were used in the identification of nonlinear systems and non-Gaussian random processes and phase coupling in wave-wave interactions.

Higher-order spectral methods enable the visualization of the transfer of energy from one frequency to another, a hallmark of nonlinear phenomena that is not visible using traditional spectral methods. The paper is organized as follows. A description of HOS methods is provided, including two illustrative examples.

Higher-Order Spectra The primary benefit of higher-order spectra (HOS), also known as higher-order frequency response functions, is that they provide information regarding the interaction of frequencies due to a nonlinear process.

Generalizations Bispectra fall in the category of higher-order spectra, or polyspectra and provide supplementary information to the power spectrum. The third order polyspectrum (bispectrum) is the easiest to compute, and hence the most popular. A statistic defined analogously is the bispectral coherency or bicoherence.

In addition, The HRV signal can be analyzed using different higher order spectra (HOS) (also known as polyspectra) that are spectral representations of higher order moments or cumulants of a signal (Nikias and Raghuvver 1987). Quantification of nonlinear coupling of physiological time series has been of considerable interest during recent years.

As a result the bispectrum is particularly of use when the analyst wishes to detect quadratic (or other even powers of) nonlinearity. The next in the series of higher-order spectra is the fourth-order spectra, the trispectrum. The trispectrum is particularly useful when analysing a signal for cubic (or other odd powers of) nonlinearity.
